- Alice-Bob protocol model
- Validation with AVISPA Tool
- Conclusion on AADS
- Research project AVANTSSAR

Airplane Assets Distribution System (AADS)

AADS is a system for storage and distribution of airplane assets, including *Loadable Software Airplane Parts (LSAP)* and airplane health data

Airplane Assets Distribution System architecture

A complex distributed store-and-forward middleware with OSS components

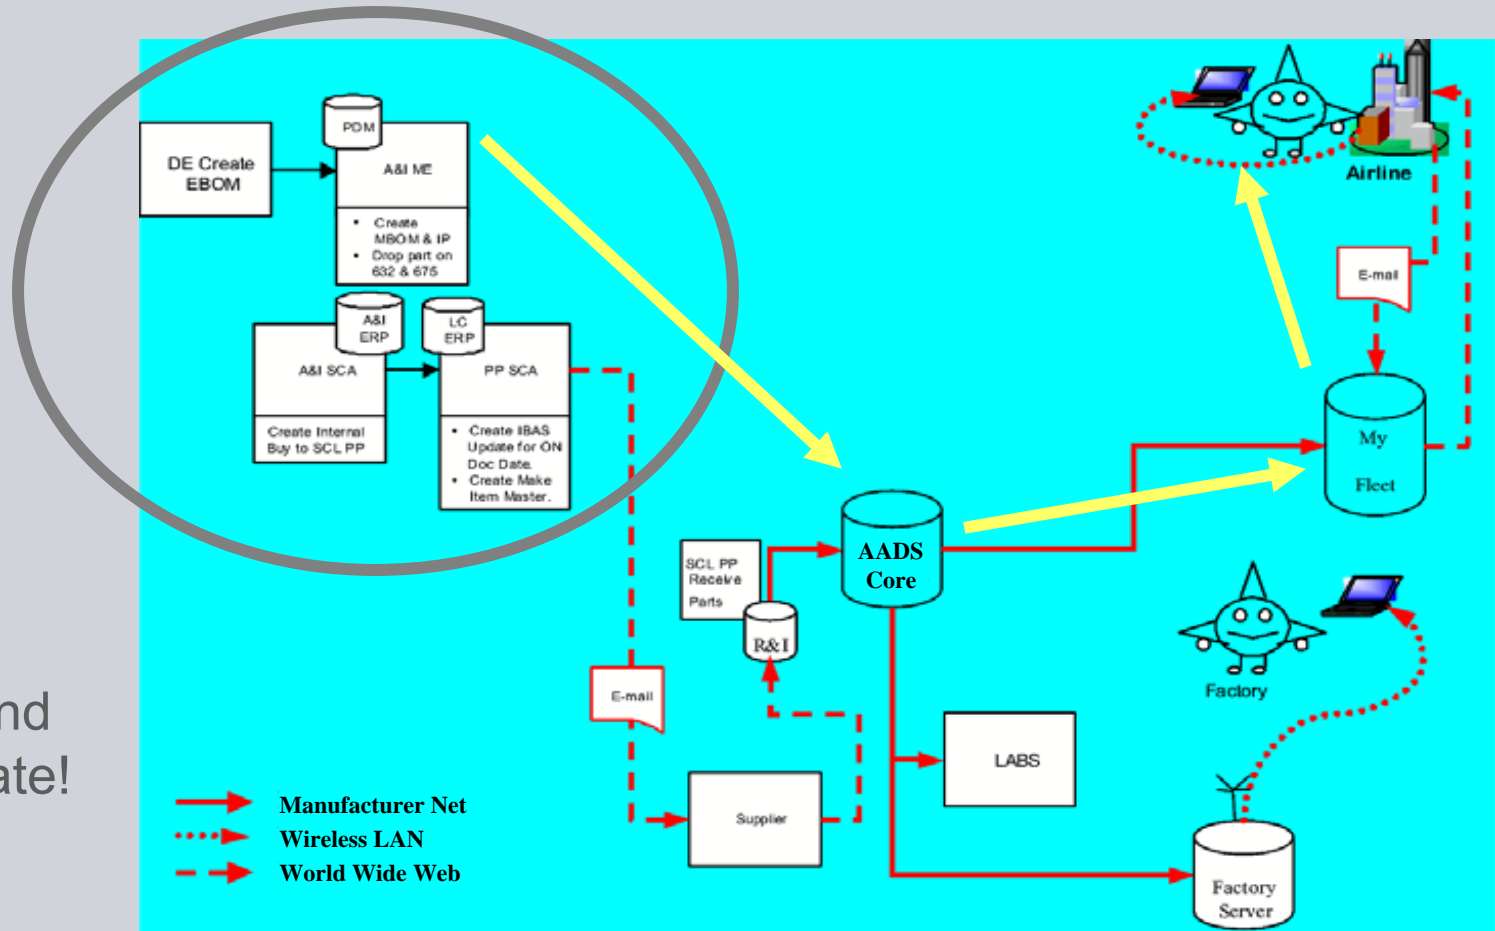

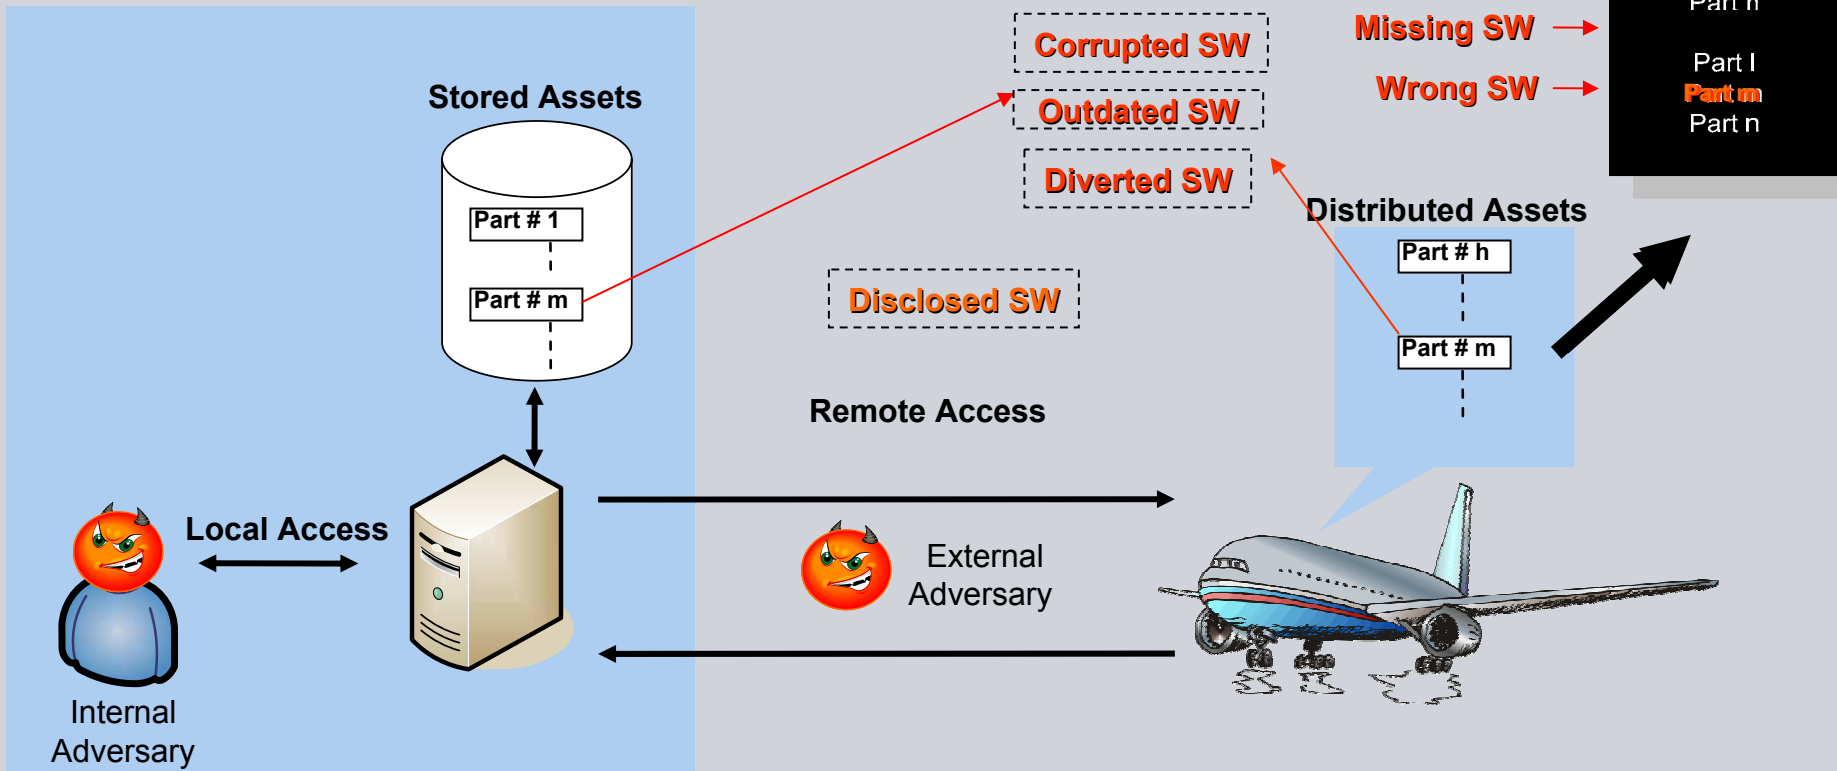

Figure is simplified and not up-to-date!

Safety-related security threats at the AADS example

Attacker's objective: lower airplane safety margins by tampering software that will be executed onboard an aircraft

Corruption/Injection

Wrong Version

Diversion

Disclosure

- Needham-Schroeder Public Key Protocol
- TLS client and server

IT Security as a System Engineering Problem

- **IT security** aims at preventing, or at least detecting, unauthorized actions by agents in an IT system.

In the AADS context, security is a prerequisite of safety.

- **Safety** aims at the absence of accidents (→ airworthiness)

Situation: security loopholes in IT systems **actively exploited**

Objective: **thwart attacks** by eliminating vulnerabilities

Difficulty: IT systems are very complex. Security is interwoven with the whole system, so **very hard to assess**.

Remedy: evaluate system following the **Common Criteria** approach

- address security **systematically in all development phases**
- perform document & code reviews and tests
- for maximal assurance, use **formal modeling and analysis**

Overview

- IT Security at Siemens Corporate Technology
- Software distribution systems
- **Common Criteria certification**
- Formal security analysis
- Alice-Bob protocol model
- Validation with AVISPA Tool
- Conclusion on AADS
- Research project AVANTSSAR

Common Criteria (CC) for IT security evaluation

product-oriented methodology
for IT security assessment

ISO/IEC standard 15408

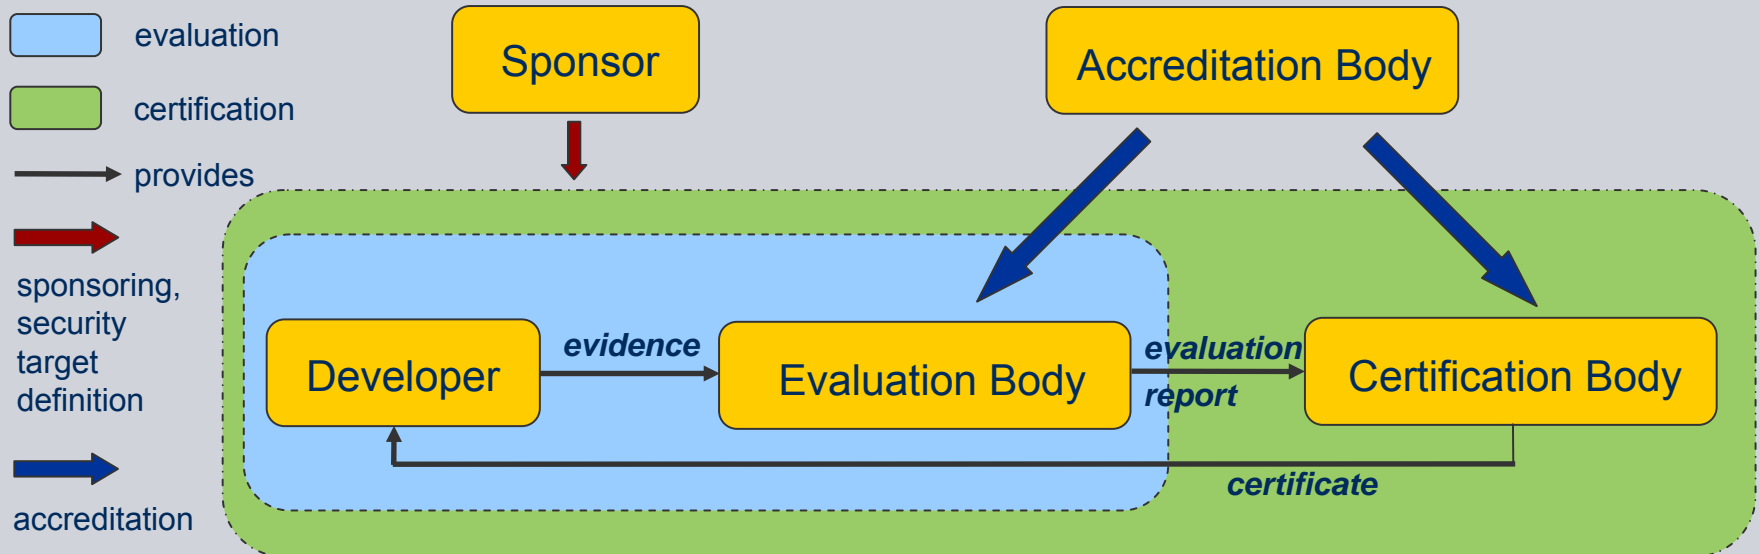

Current version: 3.1R3 of Jul 2009

Aim: gain **confidence** in the security of a system

Approach: **assessment** of system + documents **by neutral experts**

- What are the **objectives** the system should achieve?
- Are the **measures** employed **appropriate** to achieve them?
- Are the measures **implemented and deployed correctly**?

Common Criteria process overview

Certification according to the Common Criteria is a rather **complex**, **time consuming** and **expensive** process, providing **systematic assurance**.

A successful, approved evaluation is awarded a **certificate**.

Lifetime of certificates is **theoretically not bounded**, but their applicability is **limited by technical progress** (→ re-certification).

CC: Security Targets

Security Target (ST): defines extent and depth of the evaluation
for a specific product called *Target of Evaluation (TOE)*

Protection Profile (PP): defines extent and depth of the evaluation
for a whole class of products, i.e. firewalls

STs and PPs may inherit (*'claim'*) other PPs.

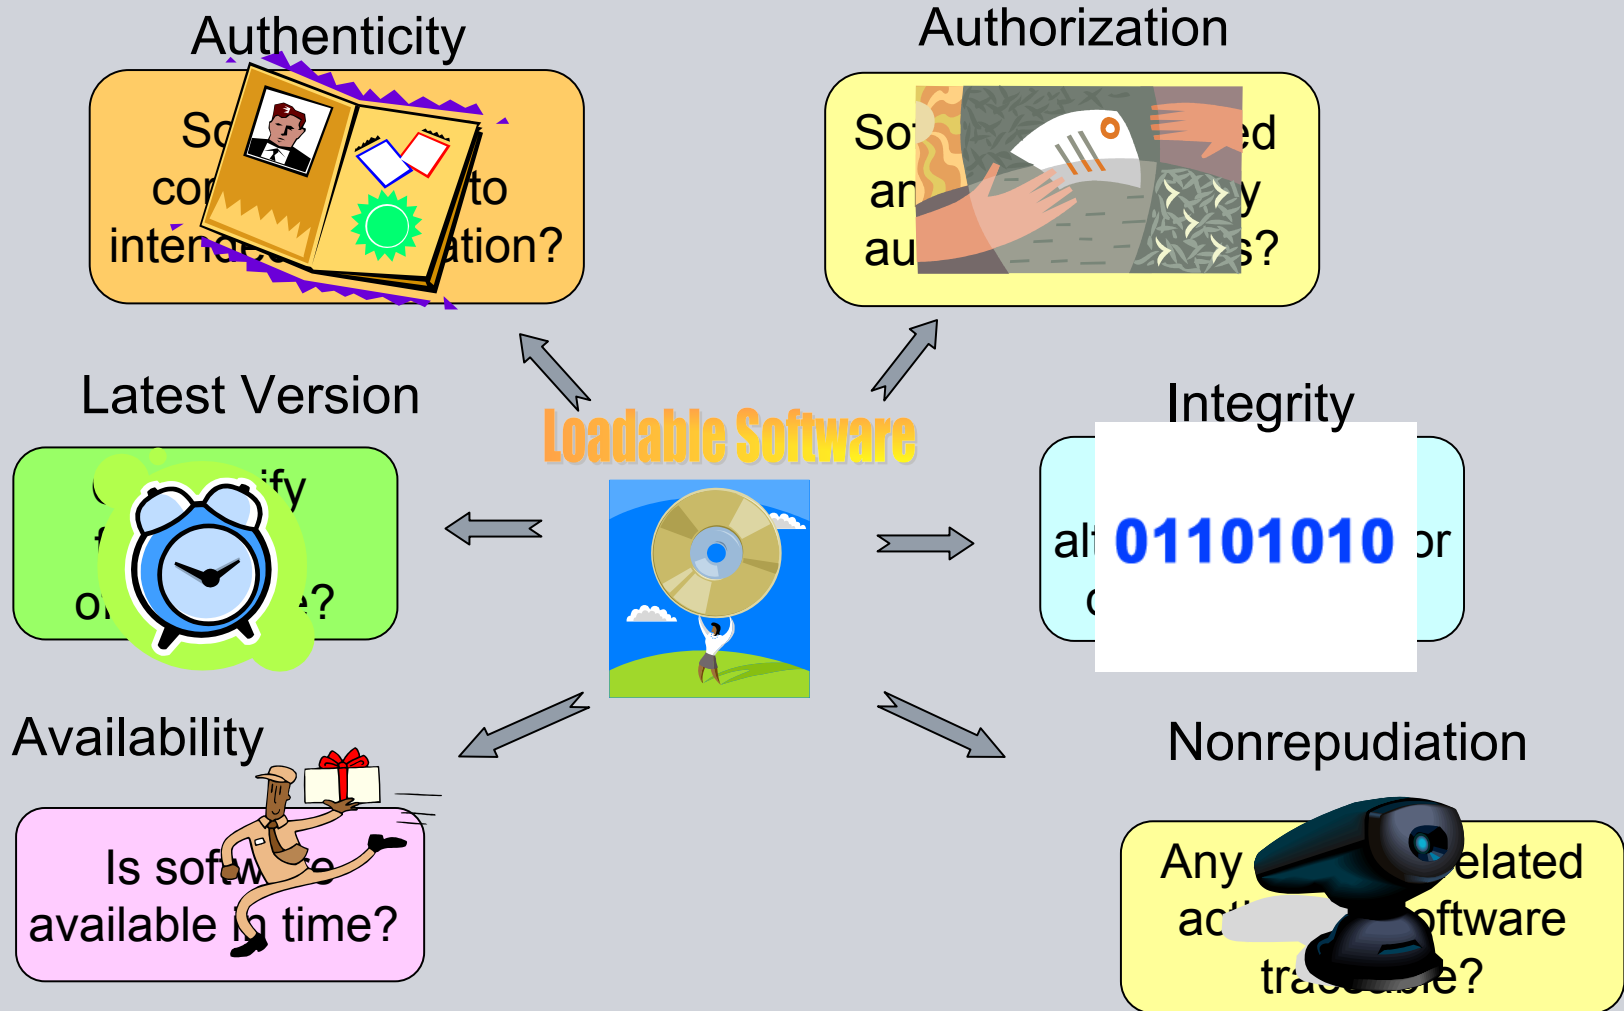

ST and PP specifications use **generic** “construction kit”:

- Building blocks for defining *Security Functional Requirements (SFRs)*
- Scalable in depth and rigor: *Security Assurance Requirements (SARs)*
layered as *Evaluation Assurance Levels (EALs)*

AADS Security Specification: CC Protection Profile (1a)

CC: Factors determining the evaluation effort

- Boundary of TOE vs. TOE environment
- Definition of Threats and Security Objectives for the TOE
- Definition of Security Functional Requirements (SFRs)
- Selection of Evaluation Assurance Level (EAL)

Source: GAO analysis of data provided by laboratories.

Source: GAO analysis of data provided by laboratories.

Selection of Evaluation Assurance Level (EAL) for AADS

	Flight safety	Airline business
Threat Level assume sophisticated adversary with moderate resources who is willing to take XXX risk	T5: XXX = significant e.g. intl. terrorists	T4: XXX = little e.g. organized crime, sophisticated hackers, intl. corporations
Information Value violation of the protection policy would cause YYY damage to the security, safety, financial posture, or infrastructure of the organization	V5: YYY= exceptionally grave Risk: loss of lives	V4: YYY = serious Risk: airplanes out of service, or damage airline reputation
Evaluation Assurance Level for the given Treat Level and Information Value	EAL 6: semiformally verified design and tested	EAL 4: methodically designed, tested, and reviewed

Evaluating the whole AADS at EAL 6 would be extremely costly.

Currently available Public Key Infrastructure (PKI) certified only at EAL 4.

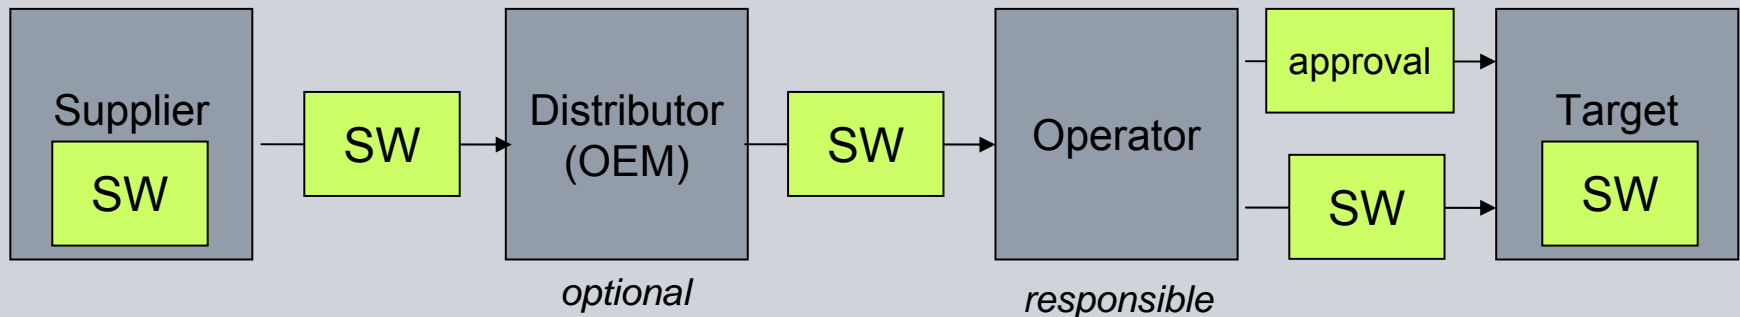

Two-level approach: evaluate only LSAP integrity & authenticity at EAL6.

Software Distribution System (SDS)

ICT systems with **networked devices** in the field performing **safety-critical** and/or **security-critical** tasks. Field devices require **secure software update**.

→ **Software Distribution System (SDS)**:

System providing secure distribution of **software (SW)** from software supplier to target devices in the field

Transition from media-based (CD-ROMs etc.) to **networked SW transport** increases **security risks** due to transport over open, untrusted networks

Software Signer Verifier (SSV)

Each node in SDS runs an SSV instance, used for:

- **Introducing** unsigned software into the SDS, by digitally signing and optionally encrypting it
- **Verifying** the signature on software received from other SSVs, checking integrity, authenticity and authorization of the sender
- **Approving** software by adding an authorized signature
- **Delivering** software out of the SDS after successfully verifying it

Hybrid security assessment

- Highest CC evaluation assurance levels (EAL 6-7) require formal analysis
- SDS usually are complex distributed systems with many components

General problems:

- Highly critical system, but (complete) formal analysis too costly
- CC offer only limited support (“CAP”) for modular system evaluation

Pragmatic approach:

- Define **confined security kernel** with generic component: SSV
- **Software Signer Verifier (SSV)** handles digital signatures at each node
- Evaluate **SSV** according to Common Criteria EAL4 (non-formal)
- Analyze the interaction of SSVs in a formal way (→ crypto protocol)

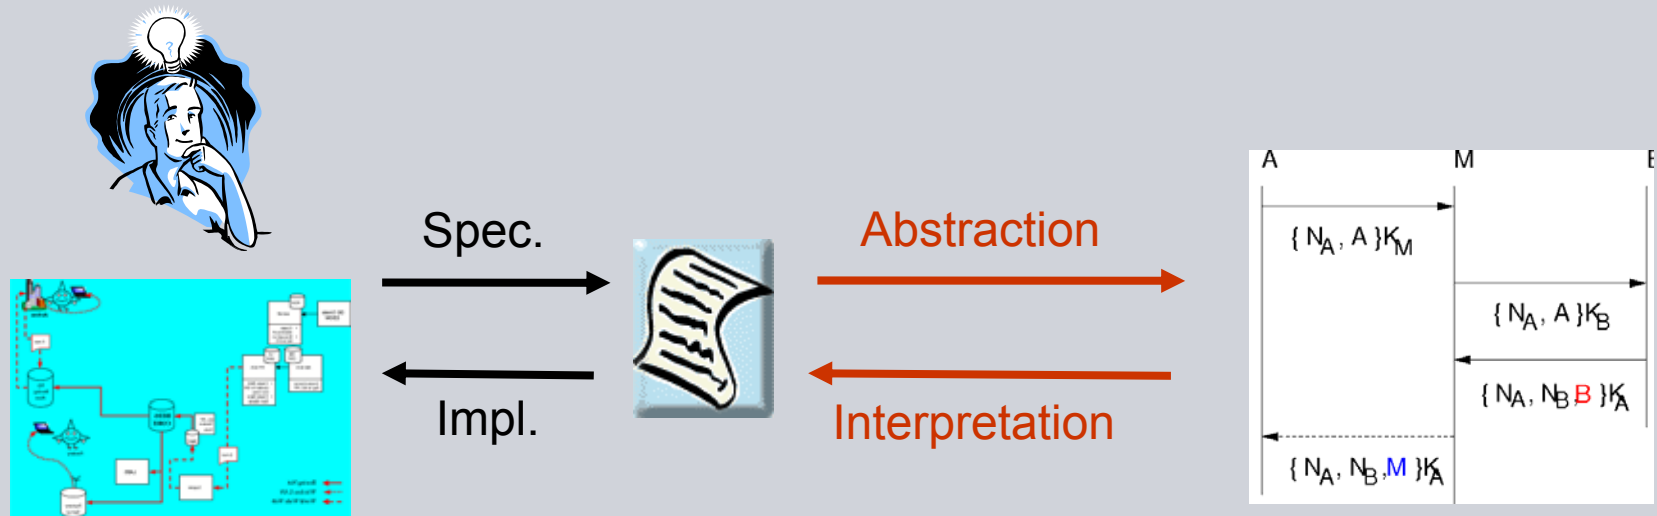

Overview

- IT Security at Siemens Corporate Technology
- Software distribution systems
- Common Criteria certification
- **Formal security analysis**
- Alice-Bob protocol model
- Validation with AVISPA Tool
- Conclusion on AADS
- Research project AVANTSSAR

Formal Security Analysis: Approach and Benefits

Mission: security analysis with **maximal precision**

Approach: **formal modeling and verification**

Improving the quality of the system **specification**

Checking for the existence of **security loopholes**

High-level protocol/system specification lang.
Model checkers (e.g., **AVANTSSAR tools**)

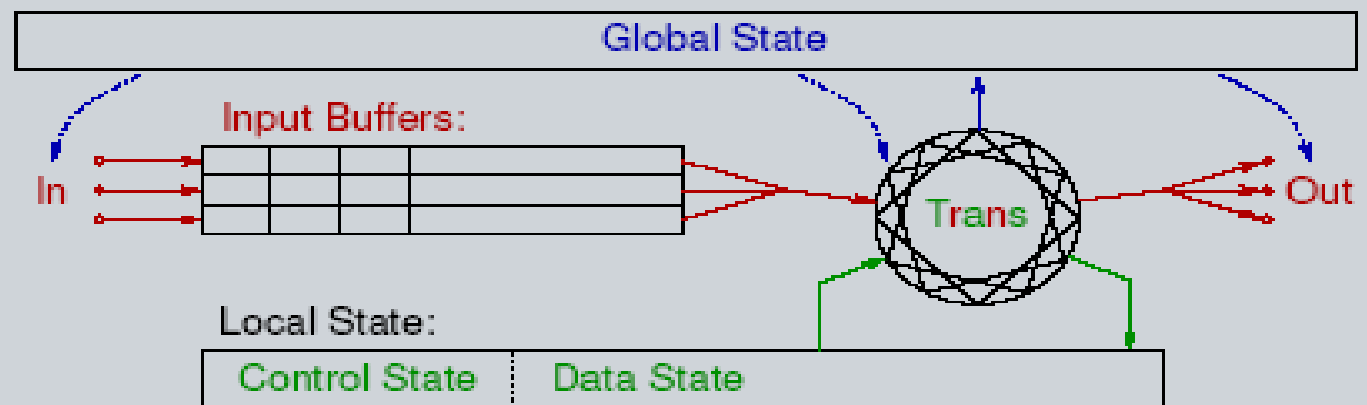

HOL, Interacting State Machines, etc.
Interactive theorem provers (e.g., **Isabelle**)

Formal Security Models

- ▶ A **security policy** defines **what is allowed** (actions, data flow, ...) typically by a relationship between **subjects** and **objects**.
- ▶ A **security model** is a (+/- formal) **description** of a policy and enforcing mechanisms, usually in terms of system **states** or state sequences (**traces**).
- ▶ **Security verification** proves that **mechanisms enforce policy**.
- ▶ Models focus on **specific characteristics** of the reality (policies).
- ▶ Types of formal security models
 - ▶ **Automata** models
 - ▶ **Access Control** models
 - ▶ **Information Flow** models
 - ▶ **Cryptoprotocol** models

Interacting State Machines (ISMs)

Automata with (nondeterministic) **state transitions** + **buffered I/O, simultaneously** on multiple connections.

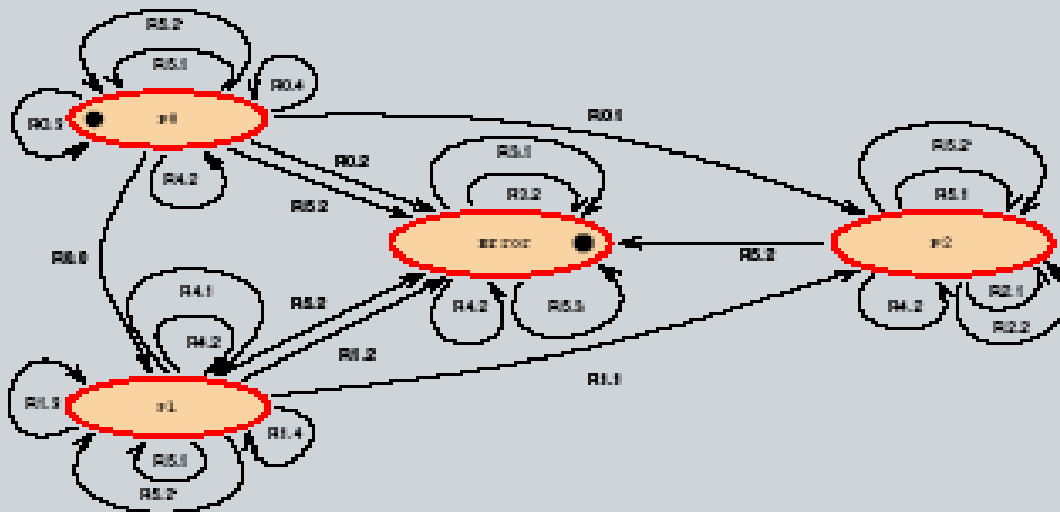

Transitions definable in executable and/or axiomatic style.
 An ISM system may have changing **global state**.
 Applicable to a large **variety of reactive systems**.
By now, not much verification support (theory, tools).

Formal model of Infineon SLE 66 Smart Card Processor

System Structure Diagram:

State Transition Diagram (abstracted):

First higher-level (EAL5) certification for a smart card processor!

Formal RBAC model of Complex Information System

Is the security design (with emergency access etc.) sound?

Privileges:

$$roles \subseteq user \times role$$

$$subroles \subseteq role \times role$$

$$privs \subseteq role \times privilege$$

Permissions:

$$groups \subseteq user \times group$$

$$subgroups \subseteq group \times group$$

$$gperms \subseteq group \times permission$$

$$uperms \subseteq user \times permission$$

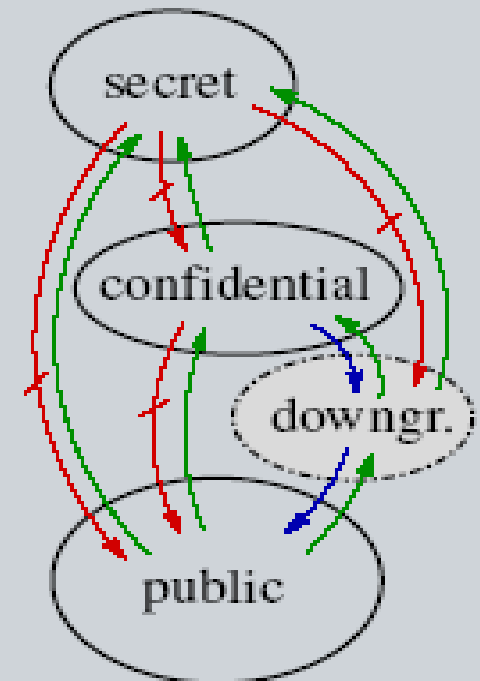

$$(u, p) \in (groups \circ subgroups^* \circ gperms(e)) \cup uperms(e)$$

“nagging questions” \rightsquigarrow clarifications improving specification quality.

Open issue: relation between model and implementation (\rightsquigarrow testing).

Information Flow Models

- ▶ Identify knowledge/information domains
 - ▶ Specify **allowed flow** between domains
 - ▶ Check the **observations** that can be made about state and/or actions
 - ▶ Consider also **indirect and partial flow**
-
- ▶ Classical model:
Noninterference (Goguen & Meseguer)
 - ▶ Many variants:
Non-deducability, Restrictiveness, Non-leakage, ...

Very strong, but rarely used in practice

Available: connection with ISMs

Language-based Information Flow Security

Policy: no assignments of **high**-values to low-variables, enforced by type system

Semantically: take (x, y) as elements of the **state space** with high-level data (**on left**) and low-level data (on right).

Step function $S(x, y) = (S_H(x, y), S_L(x, y))$

does not leak information from high to low

if $S_L(x_1, y) = S_L(x_2, y)$ (functional **independence**).

Observational equivalence $(x, y) \stackrel{L}{\sim} (x', y') \iff y = y'$

allows re-formulation:

$$s \stackrel{L}{\sim} t \longrightarrow S(s) \stackrel{L}{\sim} S(t) \quad (\text{preservation of } \stackrel{L}{\sim})$$

Generalization to action sequences α and arbitrary policies \rightsquigarrow

Cryptoprotocol models

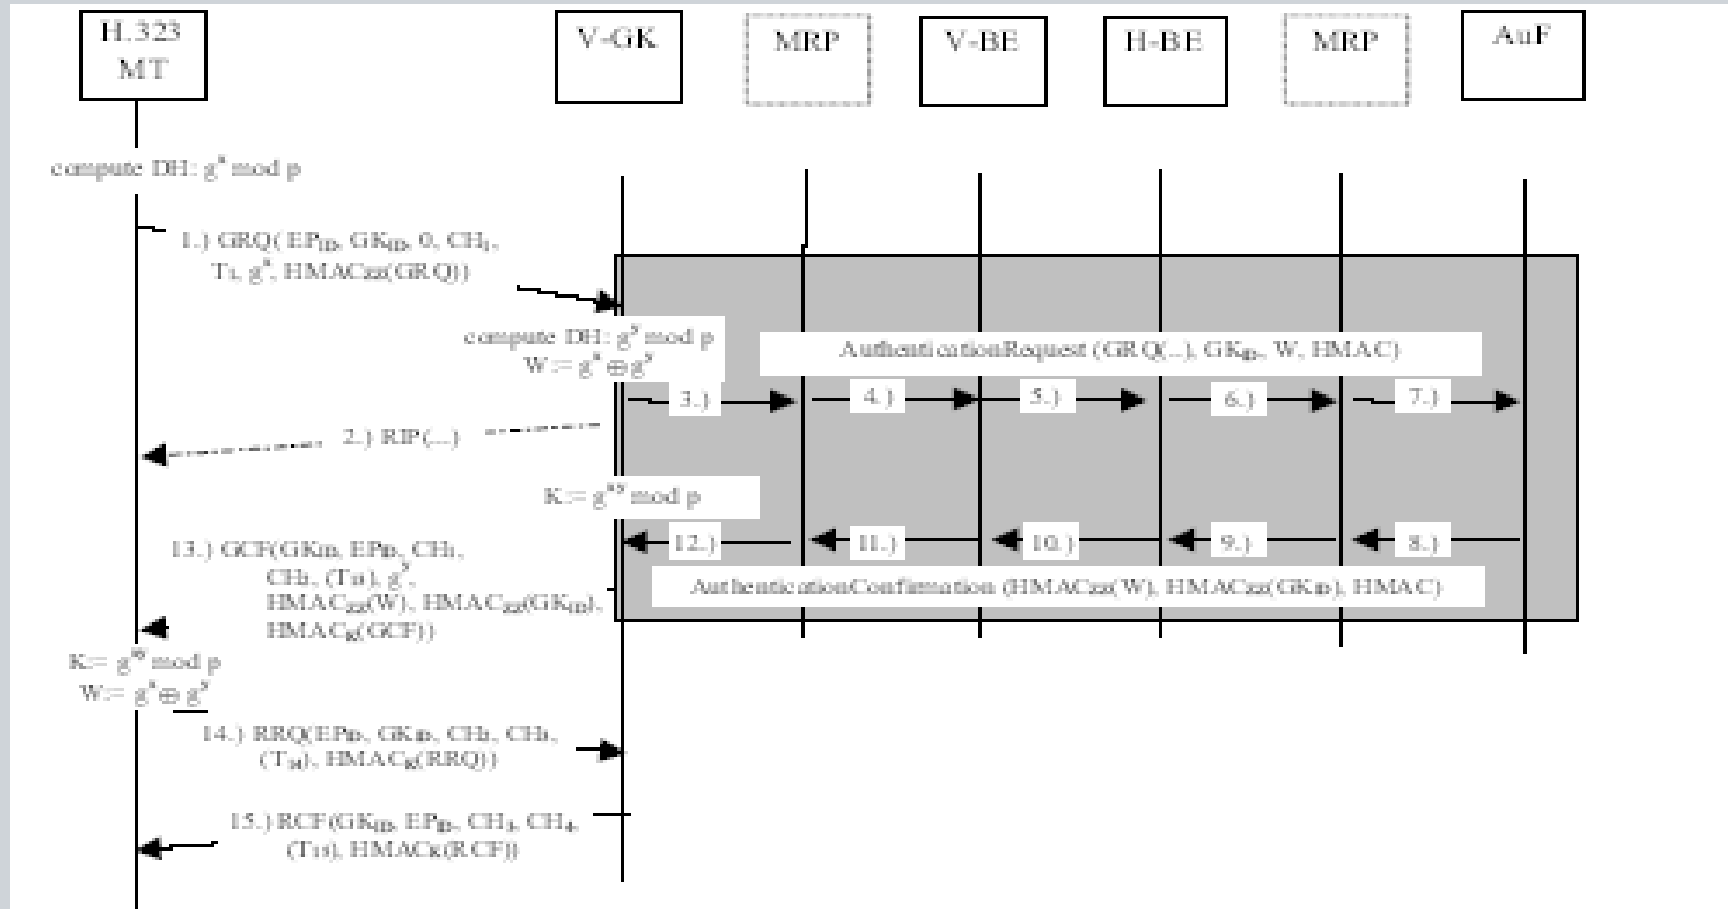

- ▶ Describe **message exchange** between processes or principals

- ▶ Take **cryptographic operations** as **perfect** primitives
- ▶ Describe system with specialized modeling languages
- ▶ State **secrecy, authentication, ...** goals
- ▶ Verify (mostly) **automatically** using model-checkers

EU project **AVISPA**, ...

Example: H.530 Mobile Roaming Authentication

Two vulnerabilities found and corrected. Solution standardized.

Overview

- IT Security at Siemens Corporate Technology
- Software distribution systems
- Common Criteria certification
- Formal security analysis
- **Alice-Bob protocol model**
- Validation with AVISPA Tool
- Conclusion on AADS
- Research project AVANTSSAR

Formal modeling: Alice-Bob notation

```

SUP - {Asset . {h(Asset) . DIS} _inv(KSUP) . CertSUP} _KDIS -> DIS
DIS - {Asset . {h(Asset) . DIS} _inv(KSUP) . CertSUP
      . {h(Asset) . OP } _inv(KDIS) . CertDIS} _KOP -> OP
OP - {Asset . {h(Asset) . DIS} _inv(KSUP) . CertSUP
     . {h(Asset) . OP } _inv(KDIS) . CertDIS
     . {h(Asset) . TD } _inv(KOP ) . CertOP } _KTD -> TD

```

$A - M -> B$ message M sent from A to B

$Asset$ a software item including its identity

$h(M)$ the hash value (i.e. cryptographic checksum) of content M

$M.N$ the concatenated contents of M and N

$\{M\}_{inv(K)}$ content M digitally signed with private key K

$\{M\}_K$ content M encrypted with public key K

Formal modeling: SDS protocol structure

```

SUP - {Asset . {h(Asset) . DIS }_inv(KSUP) . CertSUP }_KDIS -> DIS
DIS - {Asset . {h(Asset) . DIS }_inv(KSUP) . CertSUP
      . {h(Asset) . OP }_inv(KDIS) . CertDIS }_KOP -> OP
OP - {Asset . {h(Asset) . DIS }_inv(KSUP) . CertSUP
     . {h(Asset) . OP }_inv(KDIS) . CertDIS
     . {h(Asset) . TD }_inv(KOP ) . CertOP }_KTD -> TD

```

SUP : software supplier	with private key <code>inv(KSUP)</code>
DIS : software distributor	with private key <code>inv(KDIS)</code>
OP : target operator	with private key <code>inv(KOP)</code>
TD : target device	with private key <code>inv(KTD)</code>

Signatures comprise hash value of asset and **identity of intended receiver**

Signatures are applied **in parallel** (rather than nested or linearly)

Formal modeling: SDS approvals and certificates

```

SUP - {Asset. {h(Asset).DIS}_inv(KSUP). CertSUP}_KDIS -> DIS
DIS - {Asset. {h(Asset).DIS}_inv(KSUP). CertSUP
      . {h(Asset).OP}_inv(KDIS). CertDIS}_KOP -> OP
OP   - {Asset. {h(Asset).DIS}_inv(KSUP). CertSUP
      . {h(Asset).OP}_inv(KDIS). CertDIS
      . {h(Asset).TD}_inv(KOP). CertOP}_KTD -> TD

```

- Approval information partially modelled: **operator** determines **target**
- **Certificate** of a node relates its identity with its public key, e.g. certificate of supplier SUP: $\text{CertSUP} = \{\text{SUP.KSUP}\}_{\text{inv}(\text{KCA})}$
- Certificate authority (CA) with private key $\text{inv}(\text{KCA})$
- Certificates are **self-signed or signed by CA**
- Locally stored sets of public keys of trusted SSVs and CAs

Overview

- IT Security at Siemens Corporate Technology
- Software distribution systems
- Common Criteria certification
- Formal security analysis
- Alice-Bob protocol model
- **Validation with AVISPA Tool**
- Conclusion on AADS
- Research project AVANTSSAR

Verification goals

Show asset **authenticity & integrity (end-to-end)** and **confidentiality**:

- assets accepted by target have indeed been sent by the supplier
- assets accepted by target have not been modified during transport
- assets remain secret among the SSV instances

Asset authenticity & integrity **also hop-by-hop**

Correct destination covered:

- Name of the intended receiver in signed part, checked by target.
Signature of the operator acts as installation approval statement

Correct version not modelled:

- Version info is integrity protected, but
checks delegated to SSV local environment

The AVISPA model

- Alice-Bob notation not detailed and precise enough
- Use the specification language of the AVISPA Tool: **HLPSL**
- Software Signer Verifier (SSV) as **parameterized role** (node class)
- SDS as communication **protocol** linking different SSV instances
- **Multiple** protocol **sessions** describing individual SW transports

Detailed model omitted here

Results of the AVISPA tools

Details on use of the tools omitted here

Verification successful for small number of protocol sessions

- Model-checkers at their complexity limits, due to
 - parallel signatures, only the latest one being checked
 - multiple instances of central nodes (e.g. manufacturer)
 - ...?

Overview

- IT Security at Siemens Corporate Technology
- Software distribution systems
- Common Criteria certification
- Formal security analysis
- Alice-Bob protocol model
- Validation with AVISPA Tool
- **Conclusion on AADS**
- Research project AVANTSSAR

Conclusion (1) on AADS

- Challenges for AADS development
 - **pioneering** system design and architecture
 - **complex**, heterogeneous, distributed system
 - security is **critical** for both safety and business
- Common Criteria offer **adequate methodology** for assessment, at least for small components/systems
- **Systematic approach**, in particular **formal analysis**, enhances
 - **understanding** of the security issues
 - **quality** of specifications and documentation
 - **confidence** (of Boeing, customers, FAA, etc.) in the security solutions

Conclusion (2) on AADS

- Experience with SDS evaluation
 - Common Criteria **most widely accepted methodology**
 - Problem of **compositional** security evaluation not solved
 - Use formal analysis where **cost/benefit ratio** is best
 - Highly **precise design and documentation**:
 - assumptions, requirements
 - Shape system **architecture** to **support** security evaluation

- Future steps
 - **Key management** aspects:
 - Public Key Infrastructure (PKI) components etc.
 - **Configuration management**
 - with installation instructions and status/completion reports

Overview

- IT Security at Siemens Corporate Technology
- Software distribution systems
- Common Criteria certification
- Formal security analysis
- Alice-Bob protocol model
- Validation with AVISPA Tool
- Conclusion on AADS
- **Research project AVANTSSAR**

AVANTSSAR – an overview with examples

avantssar.eu

Automated Validation of Trust and Security of Service-oriented ARchitectures

EU FP7-2007-ICT-1, ICT-1.1.4, Strep project no. 216471

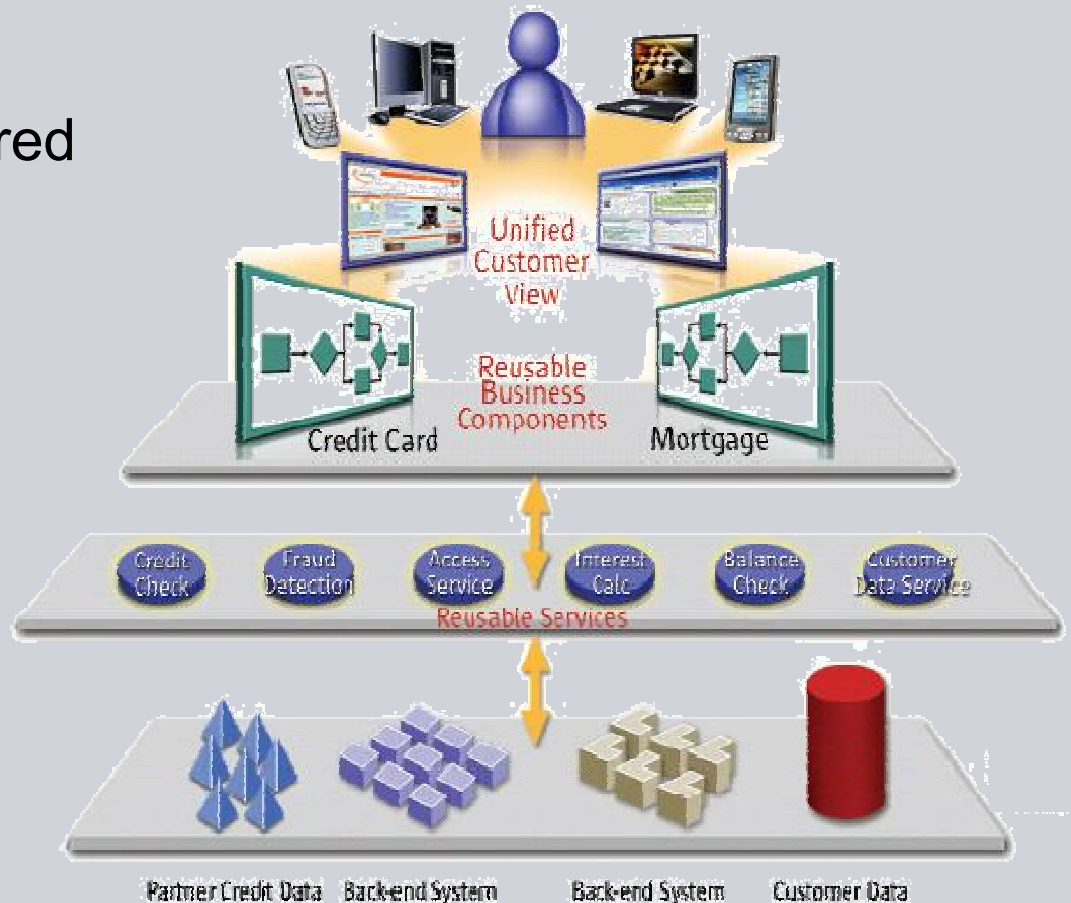

Jan 2008 - Dec 2010, 590 PMs, 6M€ budget, 3.8M€ EC contribution

AVANTSSAR project motivation

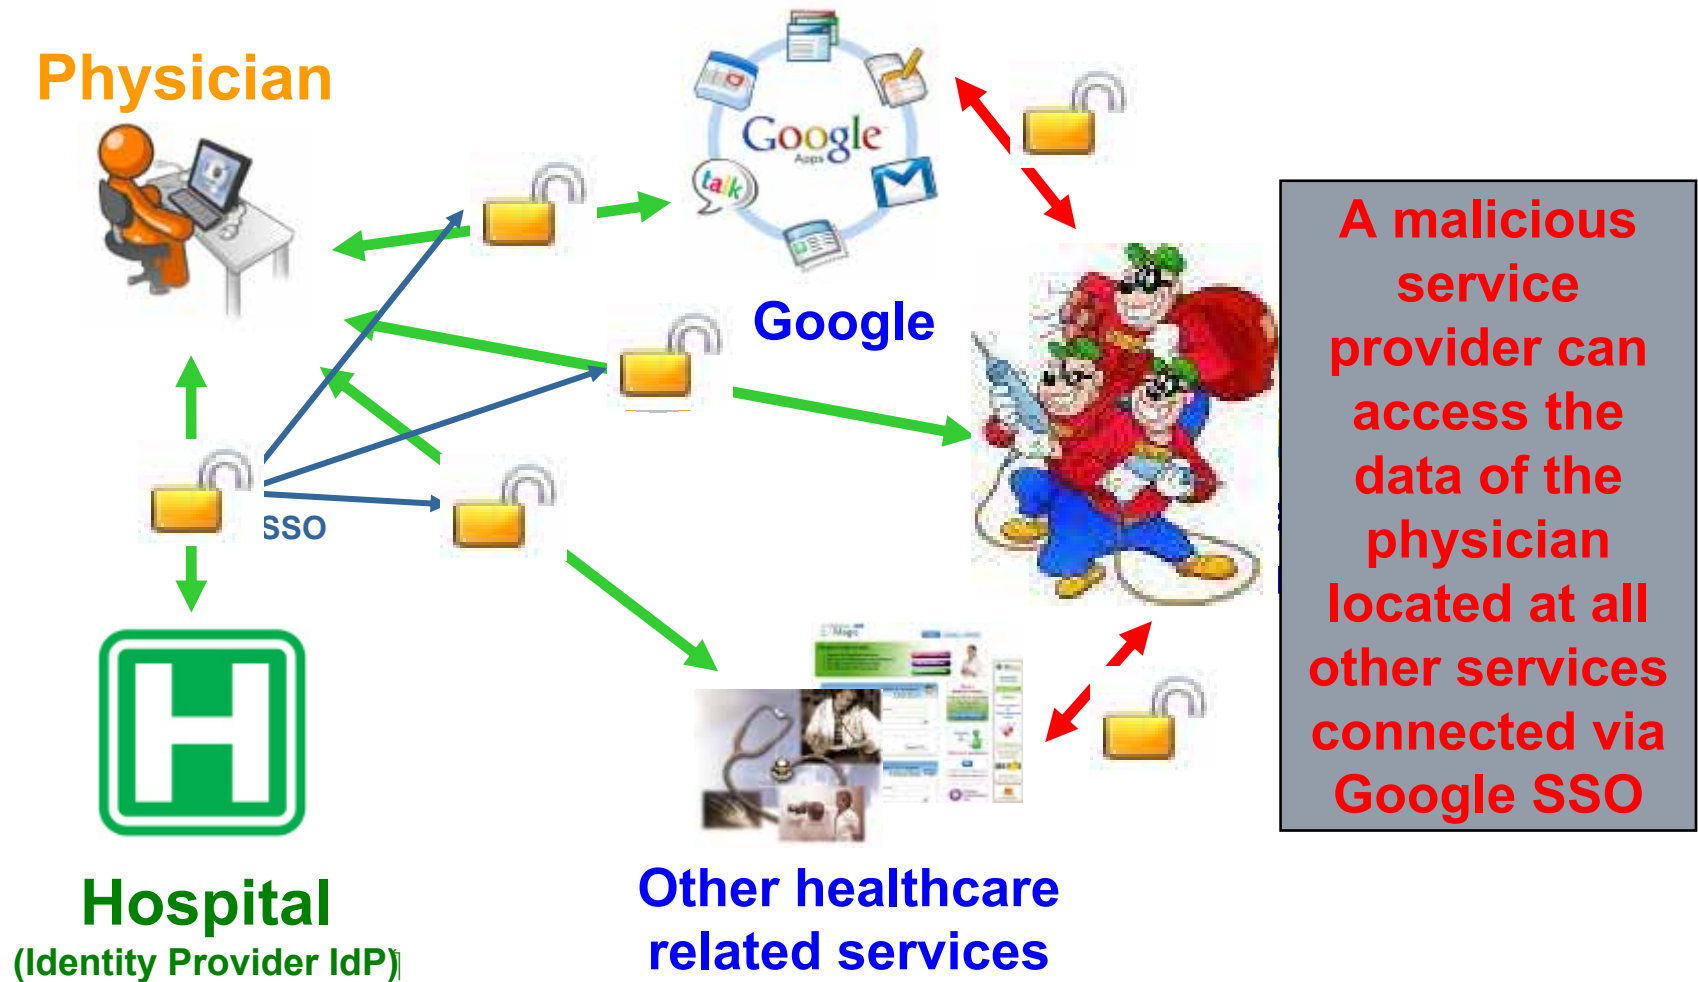

ICT paradigm shift: from components to **services**, composed and reconfigured dynamically in a demand-driven way.

Trustworthy service may **interact** with others causing novel trust and security problems.

For the composition of individual services into service-oriented architectures, **validation** is dramatically needed.

Example 1: Google SAML-based Single Sign-On (SSO)

Example 1: Google SAML SSO protocol flaw

AVANTSSAR main objectives and principles

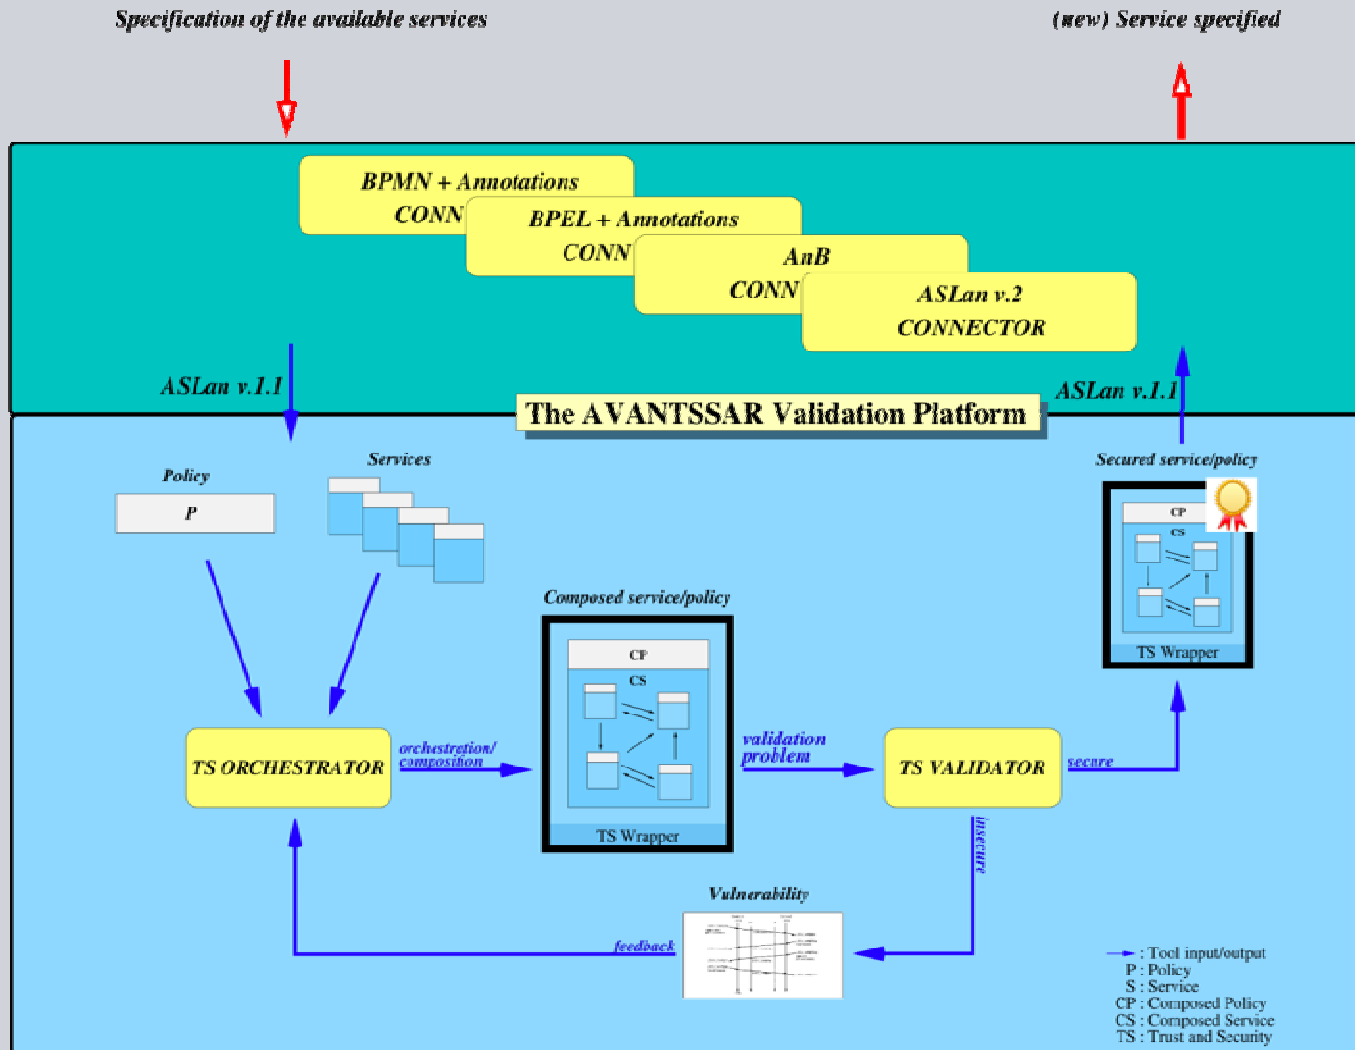

AVANTSSAR product: Platform for formal specification and automated validation of trust and security of SOAs

- **Formal language** for specifying trust and security properties of services, their policies, and their composition into service-oriented architectures
- **Automated toolset** supporting the above
- **Library** of validated industry-relevant case studies

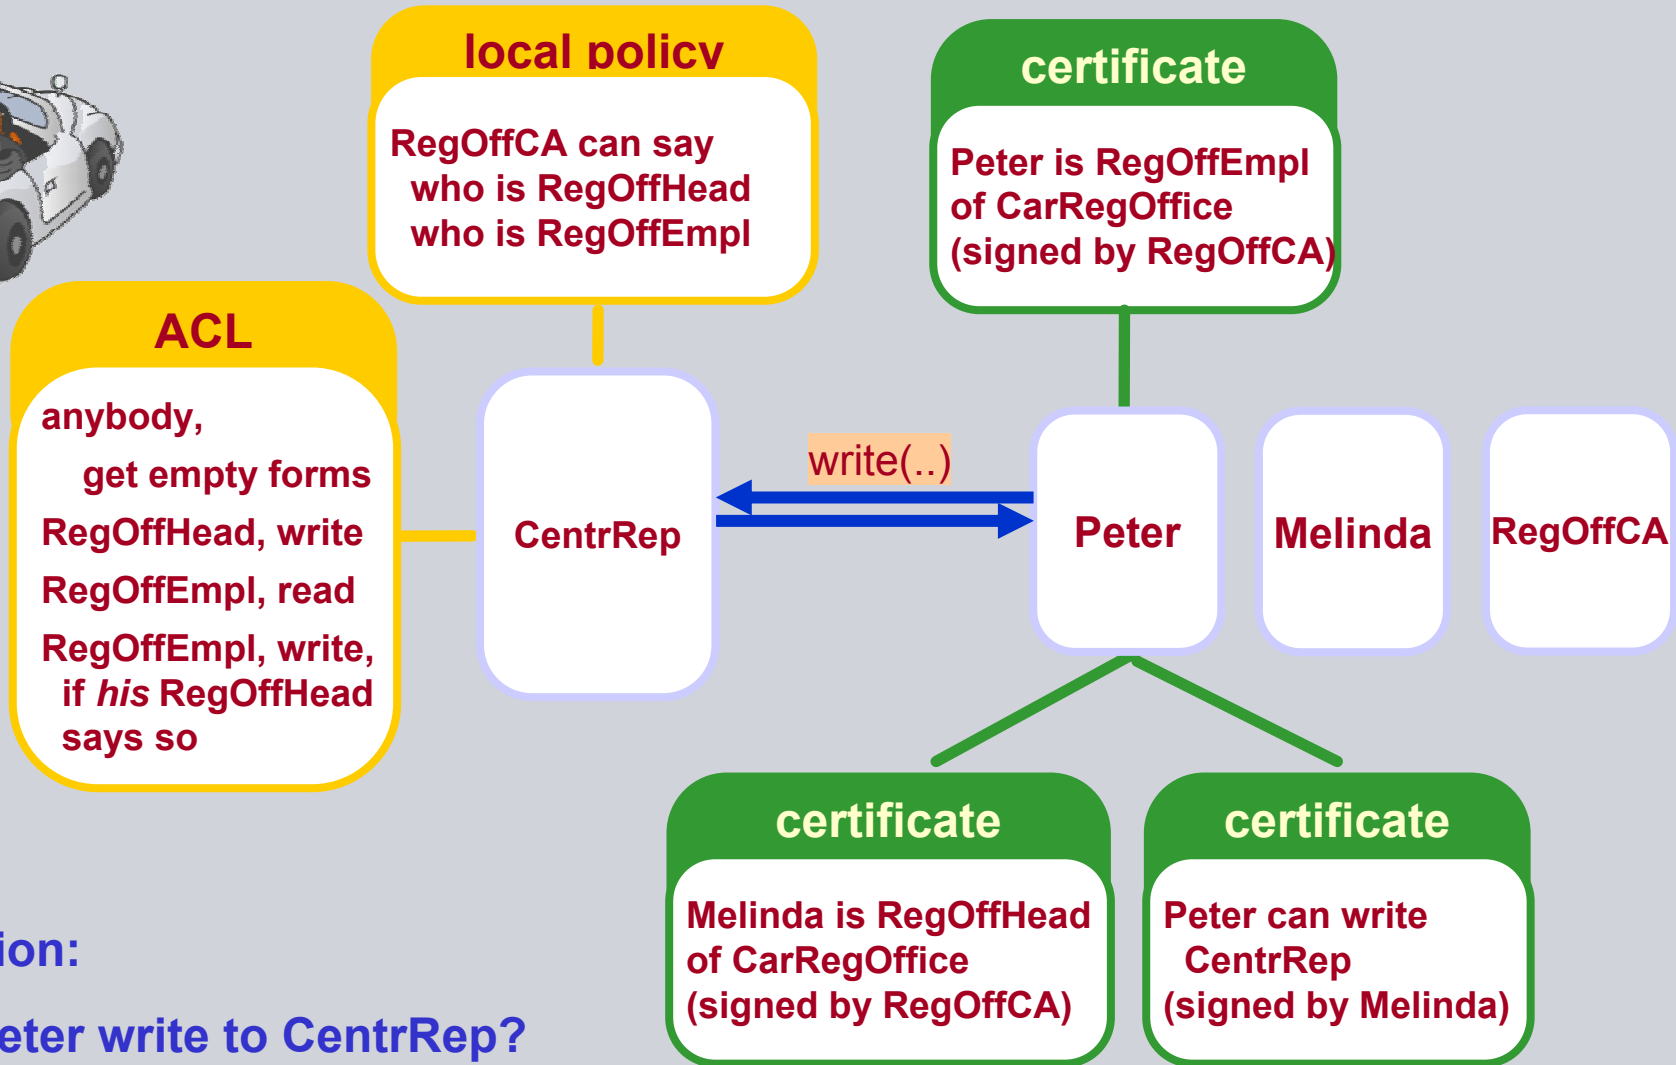

Migration of platform to industry and standardization organizations

- **Speed up development** of new service infrastructures
- **Enhance** their **security** and robustness
- **Increase public acceptance** of SOA-based systems

AVANTSSAR project results and innovation

Example 2: Electronic Car Registration policies

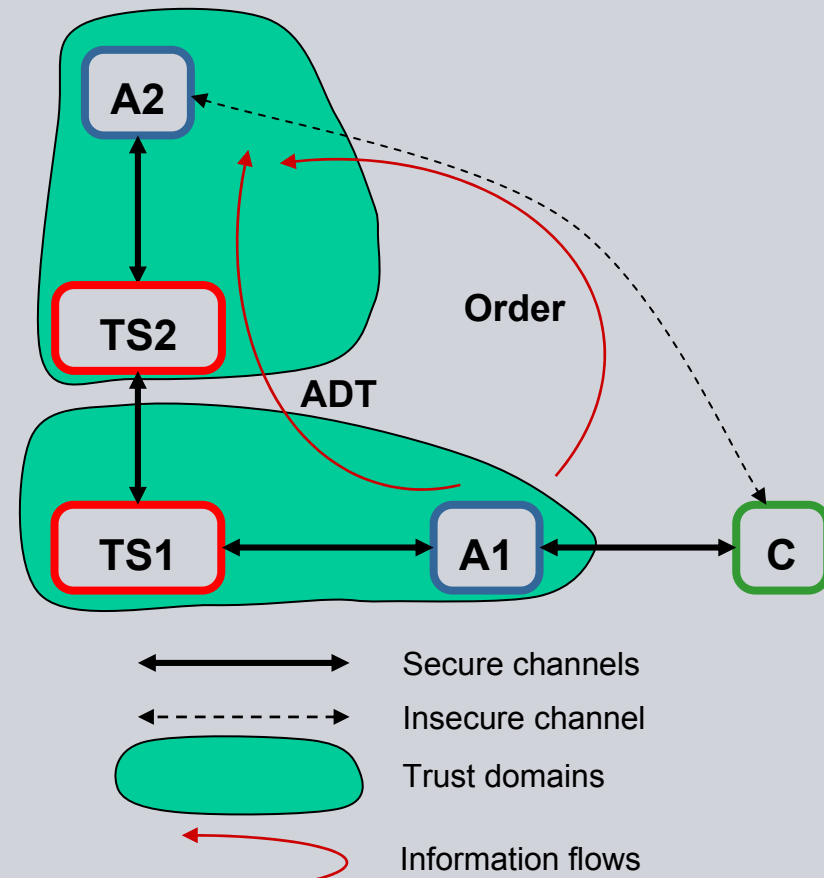

Question:

May Peter write to CentrRep?

Example 3: Process Task Delegation (PTD)

- **Authorization and trust management via token passing**
- There are three roles in the protocol (**C**, **A**, **TS**) and potentially several instances for each role
- The *client C* (or *user*) uses the system for SSO, authorization and trust management
- Each *application A* is in one domain, each domain has exactly one active *token server TS*
- **A1** uses the system to pass to **A2** some **Order** and an **ADT (Authorization Decision Token)**
 - **Order** contains:
 - workflow task information
 - application data
 - information about the client **C** and his current activity to be delivered securely (integrity and confidentiality)
 - **ADT** is mainly authorization *attributes* and *decisions*
 - sent via **TS1** and **TS2**, who may weaken it
 - must remain unaltered, apart from weakening by **TS**
 - must remain confidential among intended parties
- **C**, **A1**, and **A2** must be authenticated among each other

- **Security prerequisites:**
- PKI is used for **A** and **TS**, username & pwd for **C**
- **TS** enforces a strict time-out

Example 3: ASLan++ model of A2

```

entity A2 (Actor: agent, TS2: agent) { % Applicaton2, connected with TokenServer2
  symbols
    C0,C,A1: agent;
    CryptedOrder, Order, Order0, Details, Results, TaskHandle, ADT, HMAC: message;
    SKey: symmetric_key;
  body { while (true) {
    select {
      % A2 receives (via some C0) a package from some A1. This package includes encrypted and
      % hashed information. A2 needs the corresponding key and the Authorization Decision Token.
      on (?C0 -> Actor: (?A1.Actor.?TaskHandle.?CryptedOrder)?.?HMAC): {
        % A2 contacts its own ticket server (TS2) and requests the secret key SKey and the ADT.
        Actor *->* TS2: TaskHandle;
      }
      % A2 receives from A1 the SKey and checks if the decrypted data corresponds to the hashed data
      on (TS2 *->* Actor: (?ADT.?SKey).TaskHandle & CryptedOrder = scrypt(SKey,?Order0,?Details.?C)
        & HMAC = hmac(SKey, A1.Actor.TaskHandle.CryptedOrder)): {
        % A2 does the task requested by A1, then sends to A1 via C the results encrypted with the secret key.
        Results := fresh(); % in general, the result depends on Details etc.
        Actor -> C: Actor.C.A1. scrypt(SKey,Results);
      }
    }
  }
  goals
    authentic_C_A2_Details: C *-> Actor: Details;
    secret_Order: secret (Order0,Details.C, {Actor, A1});
}

```

AVANTSSAR current status

SIEMENS

WP2: ASLan++ supports the formal specification of trust and security related aspects of SOAs, and of static service and policy composition

WP3: Techniques for: satisfiability check of policies, model checking of SOAs w.r.t. policies, different attacker models, compositional reasoning, abstraction

WP4: Deploy first prototype of **AVANTSSAR Platform**

WP5: Formalization of **industry-relevant problem cases** as ASLan++ specifications and their validation

WP6: Ongoing dissemination and migration into scientific community and industry

Shaping a Formal Model

Formality Level: should be adequate:

- ▶ the more formal, the more **precise**,
- ▶ but requires deeper mastering of formal methods

Choice of Formalism: dependent on ...

- ▶ application domain, modeler's experience, tool availability, ...
- ▶ formalism should be **simple, expressive, flexible, mature**

Abstraction Level: should be ...

- ▶ high enough to achieve **clarity** and limit the **effort**
- ▶ low enough not to lose **important detail**

refinement allows for both high-level and detailed description

Formal Security Analysis: Information Required

- **Overview:** system architecture (components and interfaces), e.g. databases, authentication services, connections,...
- **Security-related concepts:** actors, assets, states, messages, ...
- **Threats:** which attacks have to be expected.
- **Assumptions:** what does the environment fulfill.
- **Security objectives:** what the system should achieve.
Described **in detail** such that concrete verification goals can be set up
e.g. integrity: which contents shall be modifiable by whom, at which times, by which operations (and no changes otherwise!)
- **Security mechanisms:** relation to objectives and how they are achieved.
e.g. who signs where which contents, and where is the signature checked
Described **precisely** but **at high level** (no implementation details required),
e.g. abstract message contents/format but not concrete syntax

Development Phases and the Benefits of Formal Analysis

Requirements analysis:

understanding the security issues

- **abstraction**: concentration on essentials, to keep overview
- **genericity**: standardized patterns simplify the analysis

Design, documentation:

quality of specifications

- **enforces preciseness** and **completeness**

Implementation:

effectiveness of security functionality

- formal model as precise reference for **testing and verification**

AVANTSSAR impact: industry migration

Services need to be securely combined according to evolving trust and security requirements and policies.

A rigorous demonstration that a composed SOA meets the security requirements and enforces the application policy will:

- significantly increase customers' confidence
- enable customers to fully exploit the benefits of service orientation

Integration of AVANTSSAR Platform in industrial development environment

The AVANTSSAR Platform will advance the security of industrial vendors' service offerings: **validated, provable, traceable.**

AVANTSSAR thus strengthens the competitive advantage of the products of the industrial partners.
